ABSTRACT

An experiment was carried out to study the effect of organic sources of nutrients on yield, quality, soil fertility status and economics of onion (*Allium cepa* L.) at Horticulture Research Farm, College of Horticulture, AAU, Anand during the three consecutive years 2016-17, 2017-18 and 2018-19. The experiment was laid out in Randomized Block Design with three replications and ten treatments

viz., T₁:RDF 100:75:75 NPK kg ha⁻¹ (control), T₂:100 % N from FYM, T₃:100 % N from Vermicompost, T₄: 100 % N from Castor cake, T₅:75 % N from FYM + NPK consortium 1 L ha⁻¹, T₆: 75% N from VC + NPK consortium 1 L ha⁻¹, T₇: 75% N from CC + NPK consortium 1 L ha⁻¹, T₈: 50% N from FYM + NPK consortium 1 L ha⁻¹, T₉:50% N from VC + NPK consortium 1 L ha⁻¹, T₁₀: 50% N from CC + NPK consortium 1 L ha⁻¹. Soil application of 75% N from VC + NPK consortium 1 L ha⁻¹ (T₆) and 75 % N from FYM + NPK consortium 1 L ha⁻¹ (T₅) recorded significantly, higher bulb yield (467 and 417 q/ha) and also increase organic carbon as well as soil microbial population. Higher net return (₹445672) was observed in T₆ whereas maximum BCR (5.96) recorded in T₅.

Keywords: Organic manure; TSS; microbial count; BCR.

1. INTRODUCTION

“Onion (*Allium cepa* L.) is one of the most important commercial vegetable crops grown extensively throughout the country. It is the only vegetable in which India figures prominently in the world for its production and export. In India, total area under onion cultivation is 1.639 million hectares with total production of about 26.830 MT”. Anon.2021 [1]. “In Gujarat, total area under onion cultivation is 0.082 million ha with total production of 2.109 MT with productivity of 25.71 metric tonnes” [2].

“The continuous chemical fertilizer uses deteriorated crop while organic manures improved these properties” (Mamatha, 2006). [3] “The farmers can in turn obtained good remuneration from the organically produced vegetables due to their heavy demands in national and international markets. Adoption of organic vegetable production would largely depend upon supplies of organic inputs, thoroughly backed up by well-proven production technologies. Judicious use of organic manures can maintain long term soil fertility and sustain higher productivity of crops” [1]. Therefore, keeping in view the production of onion with judicial application of organic substances along with bio fertilizers is an integrated way to reduce health hazards, to protect environment as well as enhancing production of onion.

2. MATERIALS AND METHODS

The field experiment entitle “Effect of organic sources of nutrients on yield, quality, soil fertility status and economics of onion (*Allium cepa* L.)” was laid out during the three consecutive years 2016-17, 2017-18 and 2018-19 at Horticultural Research Farm, College of Horticulture, Anand Agricultural University, Anand, Gujarat, India, during the *Rabi* season. The experiment was laid out with ten treatments *i.e.*, T₁: RDF 100:75:75

NPK kg ha⁻¹(control), T₂:100 % N from FYM, T₃:100 % N from Vermicompost, T₄: 100 % N from Castor cake, T₅:75 % N from FYM + NPK consortium 1 L ha⁻¹, T₆: 75% N from VC + NPK consortium 1 L ha⁻¹, T₇: 75% N from CC + NPK consortium 1 L ha⁻¹, T₈: 50% N from FYM + NPK consortium 1 L ha⁻¹, T₉:50% N from VC + NPK consortium 1 L ha⁻¹, T₁₀: 50% N from CC + NPK consortium 1 L ha⁻¹ in a Randomized Block Design with three replications and plot size of 3.0 × 2.0 m. The experiment was conducted in organic plot and the soil was light alluvial having sandy loam texture with 7.11 pH, 0.65% organic carbon, 240.00 kg/ha available N, 87.10 kg/ha available P₂O₅, 241.00 kg/ha available K. About six week old seedlings of white onion cv. GAWO 3 was transplanted at 15 × 10 cm spacing. The organic manures (FYM and Vermicompost) and bio-fertilizer (NPK Consortium@1 L ha⁻¹) were applied at the time of field preparation. Observation were recorded for different traits.

For yield observation five bulbs from randomly tagged plants were weighed by weighing balance and after that the average value was calculated. The quality parameters *i.e.*, TSS and Total sugar were estimated from bulbs. Soil fertility status and microbial count of soil measured at initial and after harvest of the crop. The pooled analysis was conducted in accordance with Panse and Sukhatme [4] to examine the average effect of various treatments over time.

3. RESULTS AND DISCUSSION

3.1 Yield Parameters of Onion

3.1.1 Bulb yield (q/ha)

The data on bulb yield as influenced by different treatments is presented in Table 1. The results indicated that significantly, higher bulb yield was noted with treatment T₆ during 2016-17, 2017-18, 2018-19 and in pooled analysis. In pooled

analysis treatment T6 (75% N from VC + NPK consortium 1 L ha⁻¹) recorded significantly, higher bulb yield (467 q/ha) which was at par with treatment T1 [RDF (100:75:75) NPK kg ha⁻¹] and T5 (75 % N from FYM + NPK consortium 1 L ha⁻¹). The use of vermicompost and biofertilizer (NPK consortium) may be the cause of the plant's increased vegetative growth. Because of this, there is a rise in leaf surface area, which raises photosynthetic activity and chlorophyll synthesis. This, in turn, causes the bulb to grow larger and heavier as the carbohydrates are delivered to the underground bulb, increasing yield. Similar result were also reported by Singh et al. [5], Rabari et al. [6] and Vaghela et al. [7] in onion.

3.2 Quality Parameters of Onion

3.2.1 Total soluble solids (^oBrix)

The data on Total soluble solids (^oBrix) influenced by different treatments is presented in Table 1 and results revealed that effect of different treatments on Total soluble solids (^oBrix) was found non-significant during the 2016-17, 2017-18, 2018-19 and in pooled analysis.

3.2.2 Total sugar (%)

The data on Total sugar (%) influenced by different treatments is presented in Table 1 and results revealed that effect of different treatments on Total sugar (%) was found non-significant during the 2016-17, 2017-18, 2018-19 and in pooled analysis.

3.3 Soil Parameters After Harvest of Onion

Data on soil chemical parameters as influenced by different treatments are presented in Table 2. Difference between treatments was found significant for soil EC, organic carbon, available P₂O₅ and K₂O. Whereas, soil organic carbon was found significantly higher with treatment T₃ (0.72) statistically followed by treatment T₂, T₅, T₉ and T₁₀. Higher direct incorporation of organic materials may have led to increased soil organic carbon content through subsequent decomposition of these materials, which may have contributed to the rise in organic carbon content in vermicompost applied plots. These results also collaborate with the findings of Sharma et al. [8], Sharma et al. [9], Baskar et al. [10] and Tolanur and Badanur [11]. Soil EC

(0.40) was recorded statistically the highest with treatment T8, while available P₂O₅ and K₂O were found statistically superior with treatment T1 (90.50 kg/ha and 260.07 kg/ha, respectively) over rest of the treatments.

The increase in available phosphorus content of soil due to the incorporation of organic manures may be attributed to the direct addition of phosphorus as well as solubilization of native phosphorus through release of various organic acids during the decomposition of organic matter, similar results were obtained by Kumar et al. [12] and Jamir et al. [13] and Desai et al. [14] also reported that "the application of PSB was effective when applied with inorganic P. While Increase in available K due to organic manures application may be attributed to the direct addition of potassium to the available pool of soil". "The beneficial effect of vermicompost and farmyard manure on available K might also be attributed to the reduction in fixation and release of K due to interaction of organic matter with clay besides the direct K addition to the available K pool of soil" sharma et al.[15].

3.4 Microbial Count After Harvest of Onion

The data pertaining to average microbial count after harvest influenced by different treatments is presented in Table 3 and results revealed that the treatments T5 to T10 receiving inoculation of Bio NPK consortium showed higher microbial population as compared to T1 to T4. Specifically, T5 to T10 showed 2 fold increase in Azospirillum and Azotobacter population as well as 3 fold increase in PSB and KMB population as compared to their respective controls i.e. T2 to T4. It might be due to slow releasing of nutrients from vermicompost and farm yard manure is a carrier of organic carbon and organic dry matter ultimately microbial count improved in soil with the application of vermicompost and farm yard manure alone or in combination with biofertilizers. Similar trends of results were reported Dilpreet et al. [16].

3.5 Economics of Onion

Data on economics given in Table 4 revealed that higher bulb yield (467 q/ha) and net return (₹ 445672) was observed with application of 75% N from VC + NPK consortium 1 L ha⁻¹ but higher BCR 5.96 was observed with application of 75 % N from FYM + NPK consortium 1 L ha⁻¹. These results are in line with findings of Dilpreet et al. (2017) [5] in onion.

Selling price of onion: Chemical: A grade- ₹ 1000/q, B grade- ₹ 900/q, C grade- ₹ 800/q, Organic: A grade- ₹ 1200/q, B grade- ₹ 1100/q, C grade- ₹ 1000/q

4. CONCLUSION

From the pooled results of three years, it can be concluded that application of 75% N from VC + NPK consortium 1 L ha⁻¹ or 75 % N from FYM + NPK consortium 1 L ha⁻¹ gave higher bulb yield and also increase organic carbon as well as soil microbial population. Higher net return (₹445672) was observed in 75% N from VC + NPK consortium 1 L ha⁻¹ whereas maximum BCR (5.96) recorded in 75 % N from FYM + NPK consortium 1 L ha⁻¹.
